

C/C++ Reference Card

© 2004 The Book Company

Key

```
switch - keyword, reserved  
"Hello!" - string  
// comment - commented code  
close() - library function  
main - variable, identifier  
variable - placeholder in syntax  
if (expression) - syntax  
statement;
```

Identifiers

These are ANSI C++ reserved words and cannot be used as variable names.

```
asm, auto, bool, break, case, catch, char, class, const, const_cast, continue,  
default, delete, do, double, dynamic_cast, else, enum, explicit, extern, false, float,  
for, friend, goto, if, inline, int, long, mutable, namespace, new, operator, private,  
protected, public, register, reinterpret_cast, return, short, signed, sizeof, static,  
static_cast, struct, switch, template, this, throw, true, try, typeid, typeid,  
typename, union, unsigned, using, virtual, void, volatile, wchar_t
```

Data Types

Variable Declaration

```
special class size sign type name;  
special: volatile  
class: register, static, extern, auto  
size: long, short, double  
sign: signed, unsigned  
type: int, float, char (required)  
name: the variable name (required)  
// example of variable declaration  
extern short unsigned char AFlag;  
TYPE SIZE RANGE  
char 1 signed -128 to 127  
     unsigned 0 to 255  
short 2 signed -32,768 to 32,767  
     unsigned 0 to 65,535  
long 4 signed -2,147,483,648  
     unsigned 0 - 4,294,967,295  
int varies depending on system  
float 4 3.4E +/- 38 (7 digits)  
double 8 1.7E +/- 308 (15 digits)  
long double 10 1.2E +/- 4,932 (19 digits)  
bool 1 true or false  
wchar_t 2 wide characters  
Pointers  
type *variable; // pointer to variable  
type *func(); // function returns pointer  
void * // generic pointer type  
NULL; // null pointer  
*ptr; // object pointed to by pointer  
&obj // address of object  
Arrays  
int arry[n]; // array of size n  
int arry2d[n][m]; // 2d n x m array  
int arry3d[i][j][k]; // 3d i x j x k array  
Structures  
struct name {  
    type1 element1;  
    type2 element2;  
    ...  
} object_name; // instance of name  
name variable; // variable of type name  
variable.element1; // ref. of element  
variable->element1; // reference of  
pointed to structure
```

Initialization of Variables

```
type id; // declaration  
type id,id; // multiple declaration  
type *id; // pointer declaration  
type id = value; // declare with assign  
type *id = value; // pointer with assign  
id = value; // assignment  
Example  
// single character in single quotes  
char c='A';  
// string in double quotes, ptr to string  
char *str = "Hello";  
int i = 1022;  
float f = 4.0E10; // 4^10  
int ary[2] = {1,2}; // array of ints  
const int a = 45; // constant declaration  
struct products { // declaration  
    char name[30];  
    float price;  
};  
products apple; // create instance  
apple.name = "Macintosh"; // assignment  
apple.price = 0.45;  
products *ppapple; // pointer to struct  
ppapple->name = "Granny Smith";  
ppapple->price = 0.35; // assignment
```

Exceptions

```
try {  
    // code to be tried... if statements  
    statements; // fail, exception is set  
    throw exception;  
}  
catch (type exception) {  
    // code in case of exception  
    statements;  
}
```

C++ Program Structure

```
// my first program in C++  
#include <iostream.h>  
int main ()  
{  
    cout << "Hello World!";  
    return 0;  
}  
  
// single line comment  
/* multi-line  
comment */
```

Control Structures

Decision (if-else)

```
if (condition) {  
    statements;  
}  
else if (condition) {  
    statements;  
}  
else {  
    statements;  
}  
  
if (x == 3) // curly braces not needed  
    flag = 1; // when if statement is  
else // followed by only one  
    flag = 0; // statement
```

Repetition (while)

```
while (expression) { // loop until  
    statements; // expression is false  
}  
Repetition (do-while)  
do { // perform the statements  
    statements; // as long as condition  
} while (condition); // is true
```

Repetition (for)

```
init - initial value for loop control variable  
condition - stay in the loop as long as condition is true  
increment - change the loop control variable
```

```
for(init; condition; increment) {  
    statements;  
}
```

Bifurcation (break, continue, goto, exit)

```
break; // ends a loop  
continue; // stops executing statements  
// in current iteration of loop  
// inues executing on next iteration  
label:  
goto label; // execution continues at  
            // label  
exit(rcode); // exits program
```

Selection (switch)

```
switch (variable) {  
    case constant1: // chars, ints  
        statements;  
    break; // needed to end flow  
    case constant2:  
        statements;  
    break;  
    default:  
        statements; // default statements  
}
```

Console Input/Output

[See File I/O on reverse for more about streams]

C Style Console I/O

```
stdin - standard input stream  
stdout - standard output stream  
stderr - standard error stream  
// print to screen with formatting  
printf("format", arg1,arg2,...);  
printf("nums: %d, %f, %c", 1,5.6,'C');  
// print to string s  
sprintf(s,"format", arg1, arg2,...);  
sprintf(s,"This is string # $%i",2);  
// read data from keyboard into  
// name1,name2,...  
scanf("format", &name1,&name2, ...);  
scanf("%d,%f",&var1,&var2); // read nums  
// read from string s  
sscanf("format",&name1,&name2, ...);  
sscanf(s,"%i,%c",&var1,&var2);  
C Style I/O Formatting
```

```
%d, %i integer  
%c single character  
%f double (float)  
%o octal  
%u unsigned  
%s char string  
%e, %E exponential  
%x, %X hexadecimal  
%n number of chars written  
%G, %g same as f for e,E  
C++ console I/O  
cout<< console out, printing to screen  
cin>> console in, reading from keyboard  
cerr<< console error  
clog<< console log  
cout<< "Please enter an integer: ";  
cin>>i;  
cout<<"numl: <<i<<\n<<endl;  
Control Characters  
\b backspace \f form feed \r return  
\' apostrophe \n newline \t tab  
\nnn character #nn (octal) \" quote  
\NN character #NN (hexadecimal)
```

User Defined DataTypes

```
typedef existingtype newtypename;  
typedef unsigned int WORD;  
enum name{val1, val2, ...} obj_name;  
enum days_t {MON,WED,FRI} days;  
union model_name {  
    type1 element1;  
    type2 element2; ...  
} object_name;  
union mytypes_t {  
    char c;  
    int i;  
} mytypes;  
struct packed { // bit fields  
    unsigned int flagA:1; // flagA is 1 bit  
    unsigned int flagB:3; // flagB is 3 bit  
}
```

Preprocessor Directives

```
#define ID value // replaces ID with  
// value for each occurrence in the code  
#undef ID // reverse of #define  
#ifdef ID // executes code if ID defined  
#ifndef ID // opposite of #ifdef  
#if expr // executes if expr is true  
#else // else if  
#endif // ends if block  
#line number "filename"  
// line controls what line number and  
// filename appear when a compiler error  
// occurs  
#error msg // reports msg on compl. error  
#include "file" // inserts file into code during compilation  
#pragma // passes parameters to compiler
```

Functions

In C, functions must be prototyped before the **main** function, and defined after the **main** function. In C++, functions may, but do not need to be, prototyped. C++ functions must be defined before the location where they are called from.

// function declaration

```
type name(arg1, arg2, ...){  
    statement1;  
    statement2;  
    ...  
}
```

type - return type of the function

name - name by which the function is called

arg1, arg2 - parameters to the function

statement - statements inside the function

// example function declaration

```
// return type int  
int add(int a, int b) { // parms  
    int r; // declaration  
    r = a + b; // add nums  
    return r; // return value  
}
```

// function call

```
num = add(1,2);
```

Passing Parameters

Pass By Value

```
function(int var); // passed by value  
Variable is passed into the function and can be  
changed, but changes are not passed back.
```

Pass By Constant Value

```
function(const int var);
```

Variable is passed into the function but cannot be
changed.

Pass By Reference

```
function(int &var); // pass by reference
```

Variable is passed into the function and can be
changed, changes are passed back.

Pass By Constant Reference

```
function(const int &var);
```

Variable cannot be changed in the function.

Passing an Array by Reference

It's a waste of memory to pass arrays and
structures by value, instead pass by reference.

```
int array[1]; // array declaration  
ret = arfunc(array); // function call  
int arfunc(int *array[1]) {  
    array[0] = 2; // function  
    return 2; // declaration  
}
```

Default Parameter Values

```
int add(int a, int b=2) {  
    int r;  
    r = a + b; // b is always 2  
    return (r);  
}
```

Overloading Functions

Functions can have the same name, and same
number of parameters as long as the parameters of
are different types

// takes and returns integers

```
int divide (int a, int b) {  
    return (a/b);  
}
```

// takes and returns floats

```
float divide (float a, float b) {  
    return (a/b);  
}
```

Recursion

Functions can call themselves

```
long factorial (long n) {  
    if (n > 1)  
        return (n * factorial (n-1));  
    else  
        return (1);  
}
```

Prototyping

Functions can be prototyped so they can be used
after being declared in any order

// prototyped functions can be used

// anywhere in the program

```
#include <iostream.h>  
void odd (int a);  
void even (int a);  
int main () { ... }
```

Namespaces

Namespaces allow global identifiers under a name

Simple Namespace

```
namespace identifier {  
    namespace-body;
```

Example Namespace

```
namespace first { int var = 5; }  
namespace second { double var = 3.1416; }
```

int main () {

```
    cout << first::var << endl;  
    cout << second::var << endl;  
    return 0;
```

}

using namespace identifier;

```
Example using namespace  
namespace first { int var = 5; }  
namespace second { double var = 3.1416; }
```

```
int main () {  
    using namespace second;  
    cout << var << endl;  
    cout << (var*2) << endl;  
    return 0;
```

}

Class Reference

Class Syntax

```
class classname {
public:
    classname(parameters); // constructor
    ~classname(); // destructor
    member1;
    member2;
protected:
    member3;
...
private:
    member4;
} objectname;
// constructor (initializes variables)
classname::classname(parameters) {
}
// destructor (deletes variables)
classname::~classname() {
}

public members are accessible from anywhere
where the class is visible
protected members are only accessible from
members of the same class or of a friend class
private members are accessible from members
of the same class, members of the derived classes
and a friend class
constructors may be overloaded just like any
other function. define two identical constructors
with difference parameter lists
Class Example
class CSquare { // class declaration
public:
    void Init(float h, float w);
    float GetArea(); // functions
private: // available only to CSquare
    float h,w;
} // implementations of functions
void CSquare::Init(float hi, float wi){
    h = hi; w = wi;
}
float CSquare::GetArea(){
    return (h*w);
}
// example declaration and usage
CSquare theSquare;
theSquare.Init(8,5);
area = theSquare.GetArea();
// or using a pointer to the class
CSquare *theSquare;
theSquare->Init(8,5);
area = theSquare->GetArea();
```

Overloading Operators

Like functions, operators can be overloaded. Imagine you have a class that defines a square and you create two instances of the class. You can add the two objects together.

```
class CSquare { // declare a class
public: // functions
    void Init(float h, float w);
    float GetArea();
    CSquare operator + (CSquare);
private: // overload the '+' operator
    float h,w;
} // function implementations
void CSquare::Init(float hi, float wi){
    h = hi; w = wi;
}
float CSquare::GetArea(){
    return (h*w);
}
// implementation of overloaded operator
CSquare CSquare::operator+ (CSquare cs) {
    CSquare temp; // create CSquare object
    temp.h = h + cs.h; // add h and w to
    temp.w = w + cs.w; // temp object
    return (temp);
}
// object declaration and usage
CSquare sqr1, sqr2, sqr3;
sqr1.Init(3,4); // initialize objects
sqr2.Init(2,3);
sqr3 = sqr1 + sqr2; // object sqr3 is now
(5,7)
```

Advanced Class Syntax

Static Keyword

`static` variables are the same throughout all instances of a class.

```
static int n; // declaration
CDummy::n; // reference
```

Virtual Members

Classes may have virtual members. If the function is redefined in an inherited class, the parent must have the word `virtual` in front of the function definition

This Keyword

The `this` keyword refers to the memory location of the current object.

```
int func(this); // passes pointer to
// current object
```

Class TypeCasting

```
reinterpret_cast <newtype>(expression);
dynamic_cast <newtype>(expression);
static_cast <newtype>(expression);
const_cast <newtype>(expression);
```

Expression Type

The type of an expression can be found using `typeid`. `typeid` returns a type.

Inheritance

Functions from a class can be inherited and reused in other classes. **Multiple inheritance** is possible.

```
class CPoly { // create base polygon class
protected:
    int width, height;
public:
    void SetValues(int a, int b)
    { width=a; height=b; }
}
class COutput { // create base output
public:
    void Output(int i);
}
// CRect inherits SetValues from CPoly
// and inherits Output from COutput
class CRect: public CPoly, public COutput
{
public:
    int area(void)
    { return (width * height); }
}
// CTri inherits SetValues from CPoly
class CTri: public CPoly {
public:
    int area(void)
    { return (width * height / 2); }
}
```

Templates

Templates allow functions and classes to be reused without overloading them

```
template <class id> function;
template <typename id> function;
// ----- function example -----
template <class T>
T GetMax(T a, T b) {
    return (a>b)?a:b; // return the larger
}
void main () {
    int a=9, b=2, c;
    float x=5.3, y=3.2, z;
    c=GetMax(a,b);
    z=GetMax(x,y);
}
// ----- class example -----
template <class T>
class CPair {
    T x,y;
public:
    Pair(T a, T b){
        x=a; y=b;
    }
    T GetMax();
};
template <class T>
T Pair<T>::GetMax()
{
    // implementation of GetMax function
    T ret; // return a template
    ret = x>y?x:y; // return larger
    return ret;
}
int main () {
    Pair <int> theMax (80, 45);
    cout << theMax.GetMax();
    return 0;
}
```

Friend Classes/Functions

Friend Class Example

```
class CSquare; // define CSquare
class CRectangle {
    int width, height;
public:
    void convert (CSquare a);
}
class CSquare { // we want to use the
private: // convert function in
    int side; // the CSquare class, so
public: // use the friend keyword
    void set_side (int a) { side=a; }
    friend class CRectangle;
}
void CRectangle::convert (CSquare a) {
    width = a.side;
    height = a.side;
}
// declaration and usage
CSquare sqr;
CRectangle rect; // convert can be
sqr.set_side(4); // used by the
rect.convert(sqr); // rectangle class
```

Friend Functions

A friend function has the keyword `friend` in front of it. If it is declared inside a class, that function can be called without reference from an object. An object may be passed to it.

```
/* change can be used anywhere and can
have a CRect object passed in */
// this example defined inside a class
friend CRect change(CRect);
CRectangle recta, rectb; // declaration
rectb = change(recta); // usage
```

File I/O

```
#include <fstream.h> // read/write file
#include <fstream.h> // write file
#include <ifstream.h> // read file
File I/O is done from the fstream, ofstream, and
ifstream classes.
```

File Handles

A file must have a file handle (pointer to the file) to access the file.

```
ifstream infile; // create handle called
// infile to read from a file
ofstream outfile; // handle for writing
fstream f; // handle for read/write
```

Opening Files

After declaring a file handle, the following syntax can be used to open the file

```
void open(const char *fname, ios::mode);
fname should be a string, specifying an absolute
or relative path, including filename. ios::mode
can be any number of the following and repeat:
```

in Open for reading
out Open for writing
ate Initial position: end of file
app Every output is appended at the end of file
trunc If the file already existed it is erased
binary Binary mode

```
ifstream f; // open input file example
f.open("input.txt", ios::in);
ofstream f; // open for writing in
binary
f.open("out.txt", ios::out | ios::binary
| ios::app);
```

Closing a File

A file can be closed by calling the handle's close function

```
f.close();
```

Writing To a File (Text Mode)

The operator `<<` can be used to write to a file. Like `cout`, a stream can be opened to a device. For file writing, the device is not the console, it is the file. `cout` is replaced with the file handle.

```
ofstream f; // create file handle
f.open("output.txt") // open file
f <<"Hello World\n"<<b<<c<<endl;
```

Reading From a File (Text Mode)

The operator `>>` can be used to read from a file. It works similar to `cins`. Fields are separated in the file by spaces.

```
ifstream f; // create file handle
f.open("input.txt"); // open file
while (!f.eof()) // end of file test
    f >>a>>b>>c; // read into a,b,c
```

I/O State Flags

Flags are set if errors or other conditions occur. The following functions are members of the file object

```
handle.bad() returns true if a failure occurs in
reading or writing
handle.fail() returns true for same cases as bad()
plus if formating errors occur
handle.eof() returns true if the end of the file
reached when reading
handle.good() returns false if any of the above
were true
```

Stream Pointers

`handle.tellg()` returns pointer to current
location when reading a file

`handle.tellp()` returns pointer to current
location when writing a file

// seek a position in reading a file
handle.seekg(position);

handle.seekg(offset, direction);

// seek a position in writing a file
handle.seekp(position);

handle.seekp(offset, direction);

direction can be one of the following

ios::beg beginning of the stream

ios::cur current position of the stream pointer

ios::end end of the stream

Binary Files

`buffer` is a location to store the characters.

`numbytes` is the number of bytes to written or read.

```
write(char *buffer, numbytes);
read(char *buffer, numbytes);
```

Output Formatting

streamclass f; // declare file handle
// set output flags

```
f.flags(ios::base|flag)
```

possible flags

dec fixed hex oct

scientific internal left right

uppercase boolalpha showbase showpoint

showpos skips unitbuf

adjustfield left | right | internal

basefield dec | oct | hex

floatfield scientific | fixed

f.fill() get full character

f.fill(ch) set fill character ch

f.precision(numdigits) sets the precision for

floating point numbers to numdigits

f.put(c) put a single char into output stream

f.setf(flag) sets a flag w/value

f.width() returns the current number of

characters to be written

f.width(num) sets the number of chars to be

written

ASCII Chart

Dynamic Memory

Memory can be allocated and deallocated

Allocate Memory (C++ only)

```
pointer = new type[];
```

```
int *ptr; // declare a pointer
```

```
ptr = new int; // create a new instance
```

```
ptr = new int [5]; // new array of ints
```

Deallocate Memory (C++ only)

```
delete [] pointer;
```

```
delete ptr; // delete a single int
```

```
delete [] ptr // delete array
```

Allocate Memory (C or C++)

```
void * malloc ( nbytes ); // nbytesize
```

```
char * buffer; // declare a buffer
```

```
// allocate 10 bytes to the buffer
```

```
buffer = (char *)malloc(10);
```

```
// nelements = number elements
```

```
// size = size of each element
```

```
void * malloc (nelements, size);
```

```
int *nums; // declare a buffer
```

```
// allocate 5 sets of ints
```

```
nums = (char *)calloc(5,sizeof(int));
```

```
Reallocate Memory (C or C++)
```

```
void * realloc (*ptr, size);
```

```
Delete Memory (C or C++)
```

```
void free (*ptr);
```

ANSI C++ Library Files

The following files are part of the ANSI C++ standard and should work in most compilers.

```
<algorithm.h> <bisetset.h> <deque.h>
```

```
<exception.h> <fstream.h> <functional.h>
```

```
<iomanip.h> <iostream.h> <iosfwd.h>
```

```
<iostream.h> <iostream.h> <iterator.h>
```

```
<limits.h> <list.h> <locale.h> <map.h>
```

```
<memory.h> <new.h> <numeric.h>
```

```
<ostream.h> <queue.h> <set.h> <sstream.h>
```

```
<stack.h> <stdexcep.h> <streambuf.h>
```

```
<string.h> <typeinfo.h> <utility.h>
```

```
<valarray.h> <vector.h>
```
